Introduction

Organizations can spend millions of dollars on cybersecurity defenses and consultants. Beyond the traditional tools like firewalls, system information and event management (SIEM) and anti-virus, it is easy to get caught up in the most sophisticated threat detection using artificial intelligence, machine learning and user behavior and analytics. All of these tools have their place and can be very valuable, however, one problem looms large:

Passwords are frequently the only thing protecting confidential business plans, intellectual property, communications, network access, employee census information and customer data. Unfortunately, due to human error, negligence and simple lack of knowledge, passwords are also the weakest link in security. Attacking password issues head-on provides the maximum return on investment for security.

Employees use weak passwords, reuse them across accounts and forget them. They get frustrated, productivity is lost and security is compromised. It isn't their fault. Forrester found the average employee has 25 work accounts to manage and creating strong, unique passwords for each account is impossible. After all the lost productivity and security issues employees incur trying to create and remember passwords, they still forget and call the helpdesk. One study found that up to 50% of helpdesk calls are password-related. Forrester reports that several large companies have allocated over $1 million annually for password-related support.

It is also difficult or impossible for IT admins to track weak and reused passwords, control privileged account credentials, know what BYOD is accessing accounts and close accounts when employees move or leave. Beyond that, a system is required for compliance when the auditors come. Real tools are needed and spreadsheets don't cut it.

As your customers’ trusted advisor, you can help them take control of their employee passwords. With Keeper, every employee is provided a secure, cloud-based digital vault that stores passwords and any other critical information such as encryption keys and digital certificates. Keeper will generate strong, random passwords and automatically fill them for users. This saves them time, frustration and eliminates the need for them to remember and reuse passwords. The Keeper vault is available to employees from any device and location. For the first time ever, IT admins can get insight into the employee password strength and if they are reusing them across accounts. All of this makes the entire organization more secure, increases employee productivity, and drastically cuts helpdesk calls.

Keeper Enterprise provides tools for seamless integration into the networks you manage through AD/Open LDAP synchronization, SSO Integration, two-factor authentication, and system log reporting.
By leveraging Keeper, your MSP can gain a unique competitive advantage in security and cost savings. You will help your customers to reduce helpdesk costs, improve security, increase productivity and meet compliance standards. It is a perfect complement to your other managed services like device provisioning, SIEM, network management, and endpoint detection and response (EDR).

**Passwords Are Not Going Away**

**The Truth About Biometrics**

A common belief is that biometrics, such as fingerprint, iris or facial scans, can be used to eliminate traditional passwords. There are several reasons why this is not true.

1. In one of the most common use-cases, Touch ID (fingerprint scan) on iPhones is used to unlock the PIN, which in-turn is used to unlock the phone. Therefore, the Touch ID feature is convenient, but the phone is just as vulnerable to a weak PIN with or without the fingerprint scanner.

2. There are many use-cases where the password is required to derive an encryption key. The PBKDF2 algorithm very securely converts the user’s master password to an encryption key to decrypt important data. This method eliminates the need to store the encryption keys on the device. Since biometrics are always based on an approximation, they can never be reliably converted to an encryption key. Similar to the Touch ID case above, biometrics can only be used to unlock encryption keys stored on the device. This means those encryption keys may be vulnerable to attack.

3. Biometrics can’t be changed, so if the corresponding file is ever compromised, then the user has to revert back to passwords.

4. Finally, despite most mobile devices coming with biometrics, a complete organization deployment means scanners have to be deployed to every computer and appliance and connected to a central authentication system. The costs of integration, broken and lost scanners and the liability of storing employee biometric files explain why biometrics has not been widely deployed already.

Biometrics remain a great option to use in conjunction with passwords when strong (two-factor) authentication is required, but passwords are here to stay for the foreseeable future.

**Single Sign-On (SSO) Isn’t a Silver Bullet**

SSO was created to solve many of the issues associated with passwords, but most legacy and even many newer applications don’t support the SAML protocols. Many privileged access accounts don’t support SAML or even use passwords, so storing encryption keys (SSH, AES, RSA), digital certificates and access keys are use-cases that SSO doesn’t address. Enterprises that use SSO should use a password manager to complement their SSO deployment and fill these potential gaps.

For small and medium businesses (SMBs) a password manager may be the complete identity and access management (IAM) solution due to the flexibility to work with any application, website, or privileged assets like servers, databases and network appliances. Additionally, SMBs may not have the money, time or expertise for full SSO integration.
People Are the Weak Link in Security

Keeper's Study of Ten Million Passwords that were breached by hackers shows that common employee password practices are the greatest interior security threat in an organization. The top 25 most commonly used passwords listed below represented over 50% of the 10M passwords analyzed. Nearly 17% were “123456” alone. Hackers create and maintain “dictionary lists” of these passwords and use them first when trying to break into a website, database or service. They also know that more than 60% of all people tend to use the same password on multiple websites, services and applications, so they try them across every account they can find.

If employees aren’t using passwords on this list, then they use birthdays, addresses, names of their pets, their favorites sports team, or any number of easily guessable combinations. It isn’t their fault, it is impossible to remember strong, unique passwords for every account.

Top 25 Most Common Passwords Used in Dictionary-Based Cyberattacks

1. 123456
2. 123456789
3. qwerty
4. 12345678
5. 111111
6. 1234567890
7. 1234567
8. password
9. 123123
10. 987654321
11. qwertyuiop
12. mynoob
13. 123321
14. 666666
15. 18atcskd2w
16. 7777777
17. 1q2w3e4r
18. 654321
19. 555555
20. 3rjs1la7qe
21. google
22. 1q2w3e4r5t
23. 123qwe
24. zxcvbnm
25. 1q2w3e

Employees often give up trying to come up with unique passwords and use the same password across several accounts. The obvious issue here is if any service is breached, then the hackers immediately have access to all their other services. The Yahoo breach alone provided 3 billion credentials. Hackers can do this same analysis and build “cracking dictionaries” that they use for “credential stuffing” attacks. In other words, they try the most popular passwords and have a very impressive success rate.

Other employee tactics include storing passwords on sticky notes or in a spreadsheet or other electronic document. Also, most browsers today offer to store passwords and automatically logs in when they visit a site. Now a hacker doesn’t even have to be that clever in attacking the passwords. All they need is physical access to the computer, or in the case of storing passwords in spreadsheets or browsers, remote access through a means like RDP. If this sounds far-fetched, consider that Trustwave found that remote access was the top contributor (29.7%) to breaches, ahead of phishing (18.8%).

© 2019 Keeper Security, Inc.
Bring your own device (BYOD) policy, where employees are allowed to use their personal devices for work, provides companies with flexibility, reduces costs and increases productivity. BYOD also opens the door to security, administration and compliance issues. When employees use personal devices to log in to work accounts, they need the passwords and again, store them in files or in the browser, compounding the problems with those solutions.

Even privileged users (IT admins) often share a spreadsheet by emailing or copying them to a USB drive where they can be intercepted or lost. Copies can easily be made and there is no way to see who can access those copies or prevent employees that leave from taking them. There is no audit trail of when the passwords change or who has access to them, making compliance with any security standard impossible.

**How Keeper Enterprise Password Manager Secures Credentials and Cuts Costs**

**Employee Behavior**
Keeper enables organizations to have visibility of their password hygiene and risk factors that can result in a data breach and reduce employee productivity as a result of password-related issues. This may include excess time searching for passwords, forgotten passwords, insecure sharing of passwords and contacting the helpdesk for assistance in resetting a password. Aside from the security breach costs, the productivity losses are substantial because employees transact with login credentials throughout their entire day, across multiple sites, systems and applications.

Keeper also allows the employee to take control of their passwords and use a unique, random and high-strength password for every site, system and application. Every employee is provided a secure, cloud-based digital vault that stores passwords and any other critical information such as encryption keys and digital certificates. This saves them time, frustration and eliminates the need for them to reuse and remember passwords. The Keeper vault is available to employees from any device and location. All of this makes the entire organization more secure, increases productivity and drastically cuts helpdesk calls.

**Password Visibility**
Most businesses have limited visibility into the password practices of their employees which greatly increases cyber risk. Password hygiene cannot be improved without critical information regarding password usage and compliance. Keeper solves this by providing comprehensive password reporting, auditing, analytics and notifications. The Keeper Admin Console provides at-a-glance views of employee password strength, reuse and two-factor authentication status through the security audit screen.

**Enable Secure Bring Your Own Device (BYOD)**
A password manager is critical for companies that have a BYOD policy as the administrator has more power over the Keeper Vault regardless if the device is employee or employer owned.

Keeper Enterprise enables IT admins to control what platforms (web, browser extensions, mobile and desktop) are allowed to access Keeper Vaults. The admin has control over the logout timer, so they can ensure that the employee must log in to the vault regardless of if they have a PIN set on their device. Two-factor authentication can be required and the method can be selected.
Zero-Knowledge Architecture

Zero-Knowledge is a system architecture that guarantees the highest levels of security and privacy by adhering to the following principles:

1. Data is encrypted and decrypted at the device level (not on the server)
2. The application never stores plain text (human readable) data
3. The server never receives data in plain text
4. No Keeper employee or third-party can view the unencrypted data
5. The keys to decrypt and encrypt data are derived from the user’s master password
6. Multi-Layer encryption provides access control at the user, group and admin level
7. Sharing of data uses Public Key Cryptography for secure key distribution

The best solutions support 256-bit AES encryption and PBKDF2, which are widely accepted as the strongest forms of encryption available.

No Compromise on Cloud vs On-Premises

Cloud-based services have the allure of lower upfront and ongoing maintenance costs due to their scale. If cloud services become obsolete, a business can move rapidly without ripping out and replacing entire data centers. Businesses that are able to take advantage of these lower costs and agility have a huge advantage in the marketplace. However, many organizations hesitate moving to cloud-based services due to security concerns.

The key is the Keeper zero-knowledge encryption model, which is quite different from other cloud solutions. All of Keeper’s user-facing applications are on-device, meaning key generation and encryption/decryption is done on-premises. That gives IT admins complete control over the private keys and the physical access to the records stored in the vault. Admins may restrict platforms, locations and control every aspect of the usage model.

The cloud component of our product is purely for the synchronization of encrypted data syncing and access controls. Keeper is fanatical about protecting customer data, but in the unlikely event Keeper was hacked, the attackers could only possibly access the worthless AES-256 ciphertext.
More Than Passwords. Protect Against Trust-Based Attacks

Trust-based attacks occur when hackers are able to obtain digital certificates or encryption keys to critical services. By definition, a trust-based attack is difficult or impossible to detect. Imagine the losses and liabilities associated with these critical services:

- **Remote Access**: Networks and people are distributed worldwide so businesses have no choice but to offer it. Securing remote access requires multiple layers of SSH keys, digital Certificates for VPN and Multi-factor authentication.

- **Cloud Services**: Entire businesses are now built in the cloud. Amazon AWS, Google Cloud and Azure management all require more than usernames and passwords. IT admins need Access Keys, Secret Keys and API Keys.

- **Website**: This is the new storefront for businesses. A successful attack carried out against a digital certificate can have disastrous effects on an organization. And aside from the security aspect, expired certificates cost companies millions of dollars in lost business.

- **App Deployment**: Apple, Google and Microsoft all require the use of code signing certificates to distribute applications through their platforms. Each individual team member within a software company must be responsible for managing their own keys and ensuring that production-level keys are protected.

Keeper stores all of your private keys, digital certificates, access keys, API keys and other secret data in an encrypted digital vault. Keeper provides a simple way to access your private information across any device type or OS. With Keeper, these digital assets are fully encrypted locally on your device with 256-bit AES and the ciphertext is stored in Keeper’s Cloud Security Vault.

How Keeper Enterprise Password Manager Provides the Tools You Need for Provisioning and Compliance

**Microsoft Active Directory (AD) for Rapid Deployment and Role-Based Access Control (RBAC)**

Businesses are constantly changing with new people starting and current employees moving or leaving. Not only do people change roles, but the IT services and accounts businesses offer are constantly changing. It is impossible for the IT team to manually provision, maintain and log all of these activities needed to keep systems secure and meet compliance. Microsoft Active Directory has become the standard for centralizing user roles and access.

Keeper Bridge allows businesses running Microsoft Active Directory or Open LDAP to integrate Keeper password management software within their current systems, automatically adding any number of Nodes (organizational units), Users, Roles and Teams. Once connected, Keeper enables role-based access control (RBAC) at any Node. These controls include master password strength, masking, rotation, 2FA, IP whitelisting, biometrics, platforms, sharing and account transfers. Those controls can be cascaded to all lower Nodes if desired. Teams may be provisioned for sharing credentials. As the people move throughout the organization, Keeper keeps their roles updated through AD. This includes locking an account when an employee leaves and the ability to transfer those credentials to a trusted admin.
Single Sign-On (SSO)
The password manager should enhance any Single Sign-On solution by providing a secure password manager that stores not only login credentials and passwords, but also proprietary customer data, access credentials to restricted systems and sensitive documents.
Keeper SSO Connect is a SAML 2.0 application which leverages Keeper’s zero-knowledge security architecture to securely and seamlessly authenticate users into their Keeper Vault and dynamically provision users to the platform. SSO Connect works with popular SSO IdP platforms such as Okta, Centrify, AWS, OneLogin, Ping Identity, F5 BIG-IP APM, GSuite, Microsoft ADFS/Azure AD and JumpCloud to provide businesses the utmost in authentication flexibility.

Multi-factor Authentication Support for Additional Security
Keeper allows IT administrators to select and enforce two-factor authentication to the Keeper Vault. Options include: Text, TOTP (Google Authenticator, Authy), Smartwatch, DUO, RSA and FIDO U2F (Yubikey).

Compliance and Auditing
Right along with your SIEM, endpoint, and network management, password management solution is key to meeting global compliance standards and best practices for strong cybersecurity policies for your company. Strong password hygiene and password management systems are integral to any company’s InfoSec policy, regardless of size or industry.

Access control is part of any cybersecurity framework and passwords should be the primary focus.

- NIST Cybersecurity Framework PR.AC-1: Identities and credentials are managed for authorized devices and users
- PCI-DSS Requirement 2: Do not use vendor-supplied defaults for system passwords and other security parameters.
- PCI-DSS Requirement 8: Identify and authenticate access to system components.
- HIPAA 164.308 (a) (5) Log-in Monitoring and Password Management
- ISO 27001 A.9.4.3 Password management system: Password management systems shall be interactive and shall ensure quality passwords.

Most frameworks try not to be prescriptive because they are meant to be adaptable to any environment. Therefore, your credential management system could be done on paper or in a spreadsheet, but keeping them secure, updated and audited is impossible if you have more than a few employees and assets to protect.

Every cybersecurity framework requires audit/logging capabilities.

- NIST Cybersecurity Framework PR.PT-1: Audit/log records are determined, documented, implemented and reviewed in accordance with policy
- PCI-DSS Requirement 10: Track and monitor all access to network resources and cardholder data
- HIPAA 164.308 (a) (6) Response and Reporting
- ISO 27002 12.4.1 Event Logging
Keeper provides audit logs complete with timestamps and filters to enable rapid searches for anomalies, bad behavior or forensics.

**Conclusion**

Passwords are the “keys to the kingdom” for hackers and are their primary attack vector. Companies can spend millions on cybersecurity and many do, but a solid password manager should be the first investment for formidable, proactive protection and ROI. From a security perspective, the vast majority of breaches start with stolen or weak credentials. From a cost perspective, Keeper Enterprise will increase employee productivity and materially reduce help desk costs.

MSPs and MSSPs that offer Keeper to their customers gain a competitive advantage through this increased security, happier employees and lowered cost. Keeper Enterprise password manager offers rapid provisioning solutions for every organization, regardless of size, and can seamlessly integrate with Active Directory, LDAP and all major SSO solutions.

To learn more about how MSPs and MSSPs can take advantage of our industry-leading, privileged password management solution, please contact sales@keepersecurity.com.

Don’t Get Hacked. Get Keeper.
